Jason.E.Fulman@Dartmouth.Edu

Abstract

Probabilistic algorithms are applied to prove theorems about the finite general linear and unitary groups which are typically proved by techniques such as character theory and Moebius inversion. Among the theorems studied are Steinberg's count of unipotent elements, Rudvalis and Shindoda's work on the fixed space of a random matrix, and Lusztig's work on counting nilpotent matrices of a given rank.

1 Introduction and Background

In this work done under the guidance of Persi Diaconis, Fulman [1] defined and studied measures $M_{(u,q)}$ on the set of all partitions of all integers. The definition uses the following standard notation from pages 3-5 of Macdonald [11]. Recall that λ is said to be a partition of $n = |\lambda|$ if $\lambda_1 \geq \lambda_2 \geq \dots \geq 0$ and $\sum_i \lambda_i = n$. Refer to the λ_i as the parts of λ . Let $m_i(\lambda)$ be the number of parts of λ equal to i . Then for $q > 1$ and $0 < u < 1$ the following formula defines a measure:

$$M_{(u,q)}(\lambda) = \left[\prod_{r=1}^{\infty} \left(1 - \frac{u}{q^r}\right) \right] \frac{u^{|\lambda|}}{q^{2[\sum_{h < i} h m_h(\lambda) m_i(\lambda) + \frac{1}{2} \sum_i (i-1) m_i(\lambda)^2]} \prod_i |GL(m_i(\lambda), q)|}.$$

For $0 < u < 1$ and q a prime power, the measures $M_{(u,q)}$ have a group theoretic description. For this recall (for instance from Chapter 6 of Herstein [7]) that the conjugacy classes of $GL(n, q)$ are parameterized by rational canonical form. This form corresponds to the following combinatorial data. To each monic non-constant irreducible polynomial ϕ over F_q , associate a partition (perhaps the trivial partition) λ_ϕ of some non-negative integer $|\lambda_\phi|$. Let m_ϕ denote the degree of ϕ . The only restrictions necessary for this data to represent a conjugacy class are:

1. $|\lambda_z| = 0$
2. $\sum_\phi |\lambda_\phi| m_\phi = n$

To be explicit, and for use in Section 3, a representative of the conjugacy class corresponding to the data λ_ϕ may be given as follows. Define the companion matrix $C(\phi)$ of a polynomial $\phi(z) = z^{m_\phi} + \alpha_{m_\phi-1} z^{m_\phi-1} + \dots + \alpha_1 z + \alpha_0$ to be:

$$\begin{pmatrix} 0 & 1 & 0 & \dots & 0 \\ 0 & 0 & 1 & \dots & 0 \\ \dots & \dots & \dots & \dots & \dots \\ 0 & 0 & 0 & \dots & 1 \\ -\alpha_0 & -\alpha_1 & \dots & \dots & -\alpha_{m_\phi-1} \end{pmatrix}$$

Let $\phi_1, \dots, \phi_k$ be the polynomials such that $|\lambda_{\phi_i}| > 0$. Denote the parts of λ_{ϕ_i} by $\lambda_{\phi_i,1} \geq \lambda_{\phi_i,2} \geq \dots$. Then a matrix corresponding to the above conjugacy class data is:

$$\begin{pmatrix} R_1 & 0 & 0 & 0 \\ 0 & R_2 & 0 & 0 \\ \dots & \dots & \dots & \dots \\ 0 & 0 & 0 & R_k \end{pmatrix}$$

where R_i is the matrix:

$$\begin{pmatrix} C(\phi_i^{\lambda_{\phi_i,1}}) & 0 & 0 \\ 0 & C(\phi_i^{\lambda_{\phi_i,2}}) & 0 \\ 0 & 0 & \dots \end{pmatrix}$$

Now consider the following procedure for putting a measure on the set of all partitions of all integers. Fix u such that $0 < u < 1$. Pick a non-negative integer n such that the chance of choosing n is equal to $(1-u)u^n$. Then pick α uniformly in $GL(n, q)$ and take λ to be the partition corresponding to the polynomial $z-1$ in the rational canonical form of α (if $n=0$ take λ to be the trivial partition). Fulman [3] proves that the random partition so defined obeys $M_{(u,q)}$ measure.

The measures $M_{(u,q)}$ have further remarkable properties. To state them, we use the standard notation that $\lambda'_i = m_i(\lambda) + m_{i+1}(\lambda) + \dots$. Then the following three equations hold (for the third equation assume that $k \geq 2$)

$$\begin{aligned} \sum_{\lambda} x^{|\lambda|} M_{(u,q)}(\lambda) &= \prod_{r=1}^{\infty} \frac{(1 - \frac{u}{q^r})}{(1 - \frac{ux}{q^r})} \\ \sum_{\lambda: \lambda'_1 = k} x^{|\lambda|} M_{(u,q)}(\lambda) &= \frac{(ux)^k}{|GL(k, q)|} \frac{\prod_{r=1}^{\infty} (1 - \frac{u}{q^r})}{\prod_{r=1}^k (1 - \frac{ux}{q^r})} \\ \sum_{\lambda: \lambda_1 < k} M_{(1,q)}(\lambda) &= \prod_{\substack{r=1 \\ r=0, \pm k \pmod{2k+1}}}^{\infty} (1 - \frac{1}{q^r}) \end{aligned}$$

These equations alone, independent of their group-theoretic motivation, are strong evidence that the measures $M_{(u,q)}$ are worthy of study. The first two equations will be proved probabilistically and interpreted group theoretically in this paper. The third equation is related to the Rogers-Ramanujan identities and has group theoretic meaning. For more on this third equation, which seems to be the first appearance of the Rogers-Ramanujan identities in finite group theory, see the paper by Fulman [2].

The measures $M_{(u,q)}$ are intimately related to symmetric function theory, which is the topic of the companion paper by Fulman [3]. That paper exploits the link with symmetric functions to develop a probabilistic algorithm, called the “Young Tableau Algorithm”, for growing partitions according to the measure $M_{(u,q)}$. This and related algorithms are described in Section 2 of this paper and will be key tools of this paper.

Section 3 applies the tools of Section 2 to three settings. First, Steinberg’s count of unipotent elements is proved for $GL(n, q)$ and $U(n, q)$. Second, a deeper understanding is given to work of Rudvalis and Shinoda [12] on the fixed space of a random element of $GL(n, q)$ or $U(n, q)$. Third, Lusztig’s [10] results on nilpotent matrices of a given rank are derived probabilistically.

In principle, the algorithms of Section 2 should be useful for analyzing any conjugacy class function of $GL(n, q)$ or $U(n, q)$. The results of this paper only scratch the surface.

2 Probabilistic Algorithms

Fulman [1] develops probabilistic algorithms for growing partitions according to the measures $M_{(u,q)}$. We first describe the “Young Tableau Algorithm”. To state it, recall that one defines the diagram associated to λ as the set of points $(i, j) \in \mathbb{Z}^2$ such that $1 \leq j \leq \lambda_i$. We follow Macdonald’s convention that the row index i increases as one goes downward and the column index j increases as one goes across. So the diagram of the partition (432) is:

$$\begin{array}{cccc} \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & \\ \cdot & \cdot & & \end{array}$$

Now we state the Young Tableau Algorithm. Fulman [1] proves that for $0 < u < 1$ and $q > 1$, the algorithm always halts and that the resulting partition obeys $M_{(u,q)}$ measure.

The Young Tableau Algorithm

Step 0 Start with $N = 1$ and λ the empty partition. Also start with a collection of coins indexed by the natural numbers, such that coin i has probability $\frac{u}{q^i}$ of heads and probability $1 - \frac{u}{q^i}$ of tails.

Step 1 Flip coin N .

Step 2a If coin N comes up tails, leave λ unchanged, set $N = N + 1$ and go to Step 1.

Step 2b If coin N comes up heads, choose an integer $S > 0$ according to the following rule. Set $S = 1$ with probability $\frac{q^{N-\lambda'_1}-1}{q^{N-1}}$. Set $S = s > 1$ with probability $\frac{q^{N-\lambda'_s}-q^{N-\lambda'_{s-1}}}{q^{N-1}}$. Then increase the size of column s of λ by 1 and go to Step 1.

The following remarks may be helpful.

1. Recall that a standard Young tableau T of size n is a partition of n with each dot replaced by one of $\{1, \dots, n\}$ such that each of $\{1, \dots, n\}$ appears exactly once and the numbers increase in each row and column of T . For instance,

$$\begin{array}{cccc} 1 & 3 & 5 & 6 \\ 2 & 4 & 7 & \\ 8 & 9 & & \end{array}$$

is a standard Young tableau. The Young Tableau Algorithm is so named because numbering the dots in the order in which they are created gives a standard Young tableau.

2. As an example of the Young Tableau Algorithm, suppose we are at Step 1 with λ equal to the following partition:

$$\begin{array}{cccc} \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & & \\ \cdot & & & \end{array}$$

Suppose also that $N = 4$ and that coin 4 had already come up heads once, at which time we added to column 1, giving λ . Now we flip coin 4 again and get heads, going to Step 2b. We add to column 1 with probability $\frac{q-1}{q^4-1}$, to column 2 with probability $\frac{q^2-q}{q^4-1}$, to column 3 with probability $\frac{q^3-q^2}{q^4-1}$, to column 4 with probability 0, and to column 5 with probability $\frac{q^4-q^3}{q^4-1}$. We then return to Step 1.

There is a second way to decompose the measures $M_{(u,q)}$. This uses the so-called Young lattice, which is important in combinatorics and representation theory. The elements of this lattice are all partitions of all numbers. An edge is drawn between partitions λ and Λ if Λ is obtained from λ by adding one dot.

Theorem 1 (*Fulman [1]*) *Put weights $m_{\lambda,\Lambda}$ on the Young lattice according to the rules:*

1. $m_{\lambda,\Lambda} = \frac{u}{q^{\lambda'_1}(q^{\lambda'_1+1}-1)}$ if Λ is obtained from λ by adding a box to column 1
2. $m_{\lambda,\Lambda} = \frac{u(q^{-\lambda'_s}-q^{-\lambda'_s-1})}{q^{\lambda'_1}-1}$ if Λ is obtained from λ by adding a box to column $s > 1$

Then the following formula holds:

$$M_{(u,q)}(\lambda) = \left[\prod_{r=1}^{\infty} \left(1 - \frac{u}{q^r}\right) \right] \sum_{\gamma} \prod_{i=0}^{|\lambda|-1} m_{\gamma_i, \gamma_{i+1}}$$

where the sum is over all paths γ from the empty partition to λ , and the γ_i are the partitions along the path γ .

Remarks

1. Observe that a Young tableau T of shape λ is equivalent to a path in the Young lattice from the empty partition to λ . This equivalence is given by growing the partition λ by adding boxes in the order $1, \dots, n$ in the positions determined by T . For instance the tableau:

$$\begin{array}{ccc} 1 & 3 & 4 \\ 2 & & \end{array}$$

corresponds to the path:

$$\emptyset \rightarrow \begin{array}{c} \cdot \\ \cdot \end{array} \rightarrow \begin{array}{c} \cdot \\ \cdot \end{array} \rightarrow \begin{array}{cc} \cdot & \cdot \\ \cdot & \end{array} \rightarrow \begin{array}{ccc} \cdot & \cdot & \cdot \\ \cdot & & \end{array}$$

The proof of Theorem 1 relies on the result that the chance that the Young Tableau Algorithm outputs the standard tableau T is equal to:

$$\left[\prod_{r=1}^{\infty} \left(1 - \frac{u}{q^r}\right) \right] \prod_{i=0}^{|\lambda|-1} m_{\gamma_i, \gamma_{i+1}}$$

where γ is the path in the Young lattice which corresponds to the tableau T .

2. Note that in Theorem 1 the total weight out of the empty partition is $\frac{u}{q-1}$ and that the total weight out of any other partition λ is:

$$\begin{aligned} \frac{u}{q^{\lambda'_1}(q^{\lambda'_1+1}-1)} + \sum_{i \geq 2} \frac{u(q^{-\lambda'_i} - q^{-\lambda'_{i-1}})}{q^{\lambda'_i} - 1} &= \frac{u}{q^{\lambda'_1}(q^{\lambda'_1+1}-1)} + \frac{u}{q^{\lambda'_1}} \\ &= \frac{uq}{q^{\lambda'_1+1}-1} \\ &< 1 \end{aligned}$$

Since the sum of the weights out of a partition λ to a larger partition Λ is less than 1, the weights can also be viewed as transition probabilities, provided that one allows for halting.

3. Fulman [1] gives a third way of building partitions according to the measure $M_{(u,q)}$. That algorithm is similar to the Young Tableau Algorithm, but works by adding “horizontal strips”. It would be interesting to find applications for this third algorithm as well.

3 Applications

This section uses the algorithms of Section 2 to obtain results about the general linear and unitary groups. The concept of a “cycle index” connects the measures $M_{(u,q)}$ with these groups. The cycle index of the general linear groups is due to Kung [9] and Stong [14], though without the idea of measures on partitions. The cycle index for the unitary groups was found by Fulman [1].

1. **General Linear Group Cycle Index** Let α be an element of $GL(n, q)$ and ϕ a monic, degree m_ϕ irreducible polynomial with coefficients in F_q , the field of q elements. Let $\lambda_\phi(\alpha)$ be the partition corresponding to the ϕ in the rational canonical form of α . Then,

$$(1-u)[1 + \sum_{n=1}^{\infty} \frac{u^n}{|GL(n, q)|} \sum_{\alpha \in GL(n, q)} \prod_{\phi \neq z} x_{\phi, \lambda_\phi(\alpha)}] = \prod_{\phi \neq z} (\sum_{\lambda} x_{\phi, \lambda} M_{(u, q^{m_\phi})}(\lambda))$$

2. **Unitary Group Cycle Index** The conjugacy classes of $U(n, q) \subset GL(n, q^2)$ have a description analogous to rational canonical form for $GL(n, q)$. Given a polynomial ϕ with coefficients in F_{q^2} and non-vanishing constant term, define a polynomial $\tilde{\phi}$ by:

$$\tilde{\phi} = \frac{z^{m_\phi} \phi^q(\frac{1}{z})}{[\phi(0)]^q}$$

where ϕ^q raises each coefficient of ϕ to the q th power. Writing this out, a polynomial $\phi(z) = z^{m_\phi} + \alpha_{m_\phi-1}z^{m_\phi-1} + \dots + \alpha_1z + \alpha_0$ with $\alpha_0 \neq 0$ is sent to $\tilde{\phi}(z) = z^{m_\phi} + (\frac{\alpha_1}{\alpha_0})^q z^{m_\phi-1} + \dots + (\frac{\alpha_{m_\phi-1}}{\alpha_0})^q z + (\frac{1}{\alpha_0})^q$. Fulman [1] shows that all ϕ satisfying $\phi = \tilde{\phi}$ have odd degree.

Wall [15] proves that the conjugacy classes of the unitary group correspond to the following combinatorial data. As was the case with $GL(n, q^2)$, an element $\alpha \in U(n, q)$ associates to each monic, non-constant, irreducible polynomial ϕ over F_{q^2} a partition λ_ϕ of some non-negative integer $|\lambda_\phi|$ by means of rational canonical form. The restrictions necessary for the data λ_ϕ to represent a conjugacy class are:

- (a) $|\lambda_z| = 0$
- (b) $\lambda_\phi = \lambda_{\tilde{\phi}}$
- (c) $\sum_\phi |\lambda_\phi| m_\phi = n$

This leads to the cycle index:

$$(1-u)[1 + \sum_{n=1}^{\infty} \frac{u^n}{|U(n,q)|} \sum_{\alpha \in U(n,q)} \prod_{\phi \neq z} x_{\phi, \lambda_\phi(\alpha)}] = \prod_{\phi \neq z, \phi = \tilde{\phi}} \left(\sum_{\lambda} x_{\phi, \lambda} M_{((-u)^{m_\phi}, (-q)^{m_\phi})}(\lambda) \right) \\ \prod_{\phi \neq \tilde{\phi}} \left(\sum_{\lambda} x_{\phi, \lambda} M_{(u^{2m_\phi}, q^{2m_\phi})}(\lambda) \right)$$

It is elementary to see that $M_{(-u, -q)}$ is also a measure. The Young Tableau Algorithm can not be applied to pick from it, however, because some of the “probabilities” involved would be negative. Nevertheless, the description in terms of weights on the Young lattice (Theorem 1) does extend by replacing u and q by their negatives.

The following three elementary lemmas will be of use in the applications to follow.

Lemma 1

$$1 - u = \prod_{\phi \neq z} \prod_{r=1}^{\infty} \left(1 - \frac{u^{m_\phi}}{q^{m_\phi r}} \right)$$

PROOF: For all ϕ , perform the following substitutions in the cycle index of the general linear groups. If $|\lambda| > 0$, set $x_{\phi, \lambda} = 0$. If $|\lambda| = 0$, set $x_{\phi, \lambda} = 1$. $\square$

Lemma 2

$$1 - u = \left[\prod_{\phi \neq z, \phi = \tilde{\phi}} \prod_{r=1}^{\infty} \left(1 + (-1)^r \frac{u^{m_\phi}}{q^{m_\phi r}} \right) \right] \left[\prod_{\phi \neq \tilde{\phi}} \prod_{r=1}^{\infty} \left(1 - \frac{u^{2m_\phi}}{q^{2m_\phi r}} \right) \right]$$

PROOF: Make the same substitutions as in Lemma 1, but for the unitary groups. $\square$

Lemma 3 is elementary and is taken from page 280 of Hardy and Wright [6].

Lemma 3 *For real a, y such that $|a| \leq 1, |y| < 1$,*

$$\frac{1}{(1-ay) \cdots (1-ay^k)} = 1 + ay \frac{1-y^k}{1-y} + a^2 y^2 \frac{(1-y^k)(1-y^{k+1})}{(1-y)(1-y^2)} + \cdots$$

Application 1: Counting unipotent elements

The following theorem of Steinberg is normally proven using the Steinberg character, as on page 156 of Humphreys [8]. Recall that $\alpha \in GL(n, q)$ is called unipotent if all of its eigenvalues are equal to one.

Theorem 2 *The number of unipotent elements in a finite group of Lie type G^F is the square of the order of a p -Sylow of G^F , where p is the prime used in the construction of G^F (in the case of the classical groups, p is the characteristic of F_q).*

The goal of this application is to give a probabilistic proof of Steinberg's result for $GL(n, q)$ and $U(n, q)$. To this end, we obtain a generating function for the size of a partition λ chosen from the measure $M_{(u, q)}$.

Theorem 3

$$\sum_{\lambda} x^{|\lambda|} M_{(u, q)}(\lambda) = \prod_{r=1}^{\infty} \frac{(1 - \frac{u}{q^r})}{(1 - \frac{ux}{q^r})}$$

PROOF: Observe from the Young Tableau Algorithm that the size of the partition is equal to the total number of coins which come up heads. The $r = i$ term of the product on the right hand side corresponds to the tosses of coin i , and these terms are multiplied because the coin tosses of different coins are independent. $\square$

Corollary 1 *The number of unipotent elements of $GL(n, q)$ is $q^{n(n-1)}$.*

PROOF: Setting $x_{z-1, \lambda} = x^{|\lambda|}$ and $x_{\phi, \lambda} = 0$ for $\phi \neq z-1$ in the cycle index for $GL(n, q)$ shows that the number of unipotent elements of $GL(n, q)$ is

$$\begin{aligned} & |GL(n, q)| [u^n x^n] \frac{1}{1-u} \left(\sum_{\lambda} x^{|\lambda|} M_{(u, q)}(\lambda) \right) \left(\prod_{\phi \neq z-1} \prod_{r=1}^{\infty} \left(1 - \frac{u^{m_{\phi}}}{q^{m_{\phi} r}} \right) \right) \\ &= |GL(n, q)| [u^n x^n] \frac{1}{1-u} \left(\prod_{r=1}^{\infty} \frac{(1 - \frac{u}{q^r})}{(1 - \frac{ux}{q^r})} \right) \left(\prod_{\phi \neq z-1} \prod_{r=1}^{\infty} \left(1 - \frac{u^{m_{\phi}}}{q^{m_{\phi} r}} \right) \right) \\ &= |GL(n, q)| [u^n x^n] \prod_{r=1}^{\infty} \left(\frac{1}{1 - \frac{ux}{q^r}} \right) \\ &= q^{n(n-1)} \end{aligned}$$

The first equality comes from Theorem 3. The second equality is Lemma 1, and the third equality is Lemma 3 with $a = ux, y = \frac{1}{q}$. $\square$

A similar argument works for the unitary groups. It is well known that the order of $U(n, q)$ is $q^{\binom{n}{2}} \prod_{i=1}^n (q^i - (-1)^i)$ and its p -Sylows have size $q^{\binom{n}{2}}$.

Corollary 2 *The number of unipotent elements of $U(n, q)$ is $q^{n(n-1)}$.*

PROOF: Setting $x_{z-1, \lambda} = x^{|\lambda|}$ and $x_{\phi, \lambda} = 0$ for $\phi \neq z-1$ in the cycle index for $U(n, q)$ shows that the number of unipotent elements of $U(n, q)$ is

$$\begin{aligned} & |U(n, q)| [u^n x^n] \frac{1}{1-u} \left(\sum_{\lambda} x^{|\lambda|} M_{(-u, -q)}(\lambda) \right) \left(\prod_{\phi \neq z-1, \phi=\tilde{\phi}} \prod_{r=1}^{\infty} \left(1 + (-1)^r \frac{u^{m_{\phi}}}{q^{m_{\phi} r}} \right) \right) \left(\prod_{\phi \neq \tilde{\phi}} \prod_{r=1}^{\infty} \left(1 - \frac{u^{2m_{\phi}}}{q^{2m_{\phi} r}} \right) \right) \\ &= |U(n, q)| [u^n x^n] \frac{1}{1-u} \left(\prod_{r=1}^{\infty} \frac{(1 + (-1)^r \frac{u}{q^r})}{(1 + (-1)^r \frac{ux}{q^r})} \right) \left(\prod_{\phi \neq z-1, \phi=\tilde{\phi}} \prod_{r=1}^{\infty} \left(1 + (-1)^r \frac{u^{m_{\phi}}}{q^{m_{\phi} r}} \right) \right) \left(\prod_{\phi \neq \tilde{\phi}} \prod_{r=1}^{\infty} \left(1 - \frac{u^{2m_{\phi}}}{q^{2m_{\phi} r}} \right) \right) \\ &= |U(n, q)| [u^n x^n] \prod_{r=1}^{\infty} \left(\frac{1}{(1 + (-1)^r \frac{ux}{q^r})} \right) \\ &= q^{n(n-1)} \end{aligned}$$

The first equality comes from Theorem 3 with u and q replaced by their negatives (this substitution is valid, even though the probabilistic proof of Theorem 3 breaks down for this case). The second equality is Lemma 2. The third equality uses Lemma 3 with $a = -ux, y = -\frac{1}{q}$. $\square$

Remarks

1. The proof technique of Corollaries 1 and 2 can be used to give formulas for the number of elements of $GL(n, q)$ and $U(n, q)$ with a given characteristic polynomial. See Fulman [4] for details.
2. At least for $GL(n, q)$, there should be a proof of Steinberg's count of unipotents which is bijective (i.e. which maps a pair of elements in a p -Sylow to a unipotent element).

Application 2: Work of Rudvalis and Shinoda

Rudvalis and Shinoda [12] studied the distribution of fixed vectors for the classical groups over finite fields. Let $G = G(n)$ be a classical group (i.e. one of GL, U, Sp , or O) acting on an n dimensional vector space V over a finite field F_q (in the unitary case F_{q^2}) in its natural way. Let $P_{G,n}(k, q)$ be the chance that an element of G fixes a k dimensional subspace and let $P_{G,\infty}(k, q)$ be the $n \rightarrow \infty$ limit of $P_{G,n}(k, q)$. Rudvalis and Shinoda [12] obtained the following results for the general linear and unitary cases.

1. $P_{GL,n}(k, q) = \frac{1}{|GL(k, q)|} \sum_{i=0}^{n-k} \frac{(-1)^i q^{\binom{i}{2}}}{q^{ki} |GL(i, q)|}$
2. $P_{GL,\infty}(k, q) = [\prod_{r=1}^{\infty} (1 - \frac{1}{q^r})] \frac{(\frac{1}{q})^{k^2}}{(1 - \frac{1}{q})^2 \dots (1 - \frac{1}{q^k})^2}$
3. $P_{U,n}(k, q) = \frac{1}{|U(k, q)|} \sum_{i=0}^{n-k} \frac{(-1)^i (-q)^{\binom{i}{2}}}{(-q)^{ki} |U(i, q)|}$
4. $P_{U,\infty}(k, q) = [\prod_{r=0}^{\infty} (1 + \frac{1}{(-q)^r})] \frac{(\frac{1}{q})^{k^2}}{(1 - \frac{1}{q^2}) \dots (1 - \frac{1}{q^{2k}})}$

At first glance it is not even clear that $P_{GL,\infty}(k, q)$ and $P_{U,\infty}(k, q)$ define probability distributions in k , but as Rudvalis and Shinoda note, this follows from identities of Euler. Proofs of the above results of Rudvalis and Shinoda used Moebius version on the lattice of subspaces of a vector space and a detailed knowledge of geometry over finite fields.

Theorem 1 of the previous section will lead to probabilistic proofs of the above four equations. In particular, a probabilistic interpretation will be given to the products in the formulas for $P_{GL,\infty}(k, q)$ and $P_{U,\infty}(k, q)$. The first step is to connect the theorems of Rudvalis and Shinoda with the partitions in the rational canonical form of α .

Lemma 4 *The dimension of the fixed space of an element α of $GL(n, q)$ is equal to $\lambda_{z-1}(\alpha)'_1$ (i.e. the number of parts of the partition corresponding to the polynomial $z-1$ in the rational canonical form of α).*

PROOF: It must be shown that the kernel of $\alpha - I$, where I is the identity map, has dimension $\lambda_{z-1}(\alpha)'_1$. By the explicit description of the rational canonical form of a matrix in Section 1, it is enough to prove that the kernel of the linear map with matrix $M = C((z-1)^i) - I$ is 1 dimensional for all i (as in Section 1, $C(\phi)$ is the companion matrix of a polynomial ϕ).

Each of the first $i - 1$ rows of M sums to 0, and they are linearly independent. So it needs to be shown that the last row of M has sum 0. This follows from the fact that the coefficients of $(z - 1)^i$ sum to 0. $\square$

To proceed further, we need some more notation. Let T be a standard Young tableau with k parts. Define numbers $h_1(T), \dots, h_k(T)$ associated with T . Let $h_m(T) = T_{(m+1,1)} - T_{(m,1)} - 1$ for $1 \leq m \leq k - 1$ and let $h_k(T) = |T| - T_{(k,1)}$. So if $k = 3$ and T is the tableau

$$\begin{array}{cccc} 1 & 3 & 5 & 6 \\ 2 & 4 & 7 & \\ 8 & 9 & & \end{array}$$

then $h_1(T) = 2 - 1 - 1 = 0$, $h_2(T) = 8 - 2 - 1 = 5$, and $h_3(T) = 9 - 8 = 1$. View T as being created by the Young Tableau Algorithm. Then for $1 \leq m \leq k - 1$, $h_m(T)$ is the number of dots added to T after it becomes a tableau with m parts and before it becomes a tableau with $m + 1$ parts. $h_k(T)$ is the number of dots added to T after it becomes a tableau with k parts. The proof of Theorem 4 will show that if one conditions T chosen from the measure $M_{(u,q)}$ on having k parts, then the random variables $h_1(T), \dots, h_k(T)$ are independent geometrics with parameters $\frac{u}{q}, \dots, \frac{u}{q^k}$. This will explain the factorization on the right-hand side of the formula in Theorem 4.

Theorem 4

$$\sum_{\lambda: \lambda'_1 = k} x^{|\lambda|} M_{(u,q)}(\lambda) = \frac{(ux)^k}{|GL(k, q)|} \frac{\prod_{r=1}^{\infty} (1 - \frac{u}{q^r})}{\prod_{r=1}^k (1 - \frac{ux}{q^r})}$$

PROOF: We sum over all Young tableaux T with k parts " $x^{|T|}$ times the chance that the Tableau algorithm outputs T ". The point is that one can easily compute the probability that the Tableau algorithm produces a tableau T with given values $h_1, \dots, h_k$.

Suppose that one takes a step up along the Young lattice from a partition with m parts. Theorem 1 implies that the weight for adding to column 1 is $\frac{u}{q^m(q^{m+1}-1)}$, and that the sum of the weights for adding to any other column is $\frac{u}{q^m}$. Thus $x^{|T|}$ times the chance that the Tableau algorithm yields a tableau with given values $h_1, \dots, h_k$ is:

$$\prod_{r=1}^{\infty} (1 - \frac{u}{q^r}) \frac{(xu)^k}{|GL(k, q)|} \prod_{m=1}^k (\frac{ux}{q^m})^{h_m}$$

Summing over all possible values of $h_m \geq 0$ gives:

$$\begin{aligned} \sum_{\lambda: \sum \lambda'_1 = k} x^{|\lambda|} M_{(u,q)}(\lambda) &= \prod_{r=1}^{\infty} (1 - \frac{u}{q^r}) \frac{(ux)^k}{|GL(k, q)|} \prod_{m=1}^k [\sum_{h_m=0}^{\infty} (\frac{ux}{q^m})^{h_m}] \\ &= \prod_{r=1}^{\infty} (1 - \frac{u}{q^r}) \frac{(ux)^k}{|GL(k, q)|} \prod_{m=1}^k \frac{1}{(1 - \frac{ux}{q^m})} \\ &= \frac{(ux)^k}{|GL(k, q)|} \frac{\prod_{r=1}^{\infty} (1 - \frac{u}{q^r})}{\prod_{r=1}^k (1 - \frac{ux}{q^r})} \end{aligned}$$

$\square$

To deduce the The Rudvalis/Shinoda formulas for the general linear and unitary groups, two further easy lemmas will be used.

Lemma 5 *If $f(1) < \infty$ and f has a Taylor series around 0, then*

$$\lim_{n \rightarrow \infty} [u^n] \frac{f(u)}{1-u} = f(1)$$

PROOF: Write the Taylor expansion $f(u) = \sum_{n=0}^{\infty} a_n u^n$. Then observe that $[u^n] \frac{f(u)}{1-u} = \sum_{i=0}^n a_i$. $\square$

Lemma 6 *(Goldman and Rota [5])*

$$\prod_{r=1}^{\infty} \left(1 - \frac{u}{q^r}\right) = \sum_{i=0}^{\infty} \frac{(-u)^i}{(q^i - 1) \cdots (q - 1)}$$

The goal of our second application of the algorithms of Section 2 can now be attained.

Theorem 5 *(Rudvalis and Shinoda [12])*

1. $P_{GL,n}(k, q) = \frac{1}{|GL(k, q)|} \sum_{i=0}^{n-k} \frac{(-1)^i q^{\binom{i}{2}}}{q^{ki} |GL(i, q)|}$
2. $P_{GL,\infty}(k, q) = [\prod_{r=1}^{\infty} (1 - \frac{1}{q^r})] \frac{(\frac{1}{q})^{k^2}}{(1 - \frac{1}{q})^2 \cdots (1 - \frac{1}{q^k})^2}$
3. $P_{U,n}(k, q) = \frac{1}{|U(k, q)|} \sum_{i=0}^{n-k} \frac{(-1)^i (-q)^{\binom{i}{2}}}{(-q)^{ki} |U(i, q)|}$
4. $P_{U,\infty}(k, q) = [\prod_{r=0}^{\infty} (1 + \frac{1}{(-q)^r})] \frac{(\frac{1}{q})^{k^2}}{(1 - \frac{1}{q^2}) \cdots (1 - \frac{1}{q^{2k}})}$

PROOF: In the cycle index for the general linear groups, set $x_{z-1,\lambda} = 1$ if λ has k parts and $x_{\phi,\lambda} = 0$ otherwise. By Lemma 4, Theorem 4 with $x = 1$, and Lemma 6,

$$\begin{aligned} P_{GL,n}(k, q) &= [u^n] \frac{1}{1-u} \sum_{\lambda: \lambda'_1 = k} M_{(u,q)}(\lambda) \\ &= [u^n] \frac{u^k \prod_{r=1}^{\infty} (1 - \frac{u}{q^{k+r}})}{(1-u) |GL(k, q)|} \\ &= \frac{1}{|GL(k, q)|} [u^{n-k}] \frac{1}{1-u} \sum_{i=0}^{\infty} \frac{(-1)^i (uq^{-k})^i}{(q^i - 1) \cdots (q - 1)} \\ &= \frac{1}{|GL(k, q)|} \sum_{i=0}^{n-k} \frac{(-1)^i q^{-ki}}{(q^i - 1) \cdots (q - 1)} \end{aligned}$$

For the second part of the theorem use Lemma 5 and Theorem 4 with $x = 1, u = 1$ to conclude that:

$$\begin{aligned} P_{GL,\infty}(k, q) &= \lim_{n \rightarrow \infty} [u^n] \frac{1}{1-u} \sum_{\lambda: \lambda'_1 = k} M_{(u,q)}(\lambda) \\ &= \sum_{\lambda: \lambda'_1 = k} M_{(1,q)}(\lambda) \end{aligned}$$

$$\begin{aligned}
&= \frac{\prod_{r=k+1}^{\infty} (1 - \frac{1}{q^r})}{|GL(k, q)|} \\
&= [\prod_{r=1}^{\infty} (1 - \frac{1}{q^r})] \frac{(\frac{1}{q})^{k^2}}{(1 - \frac{1}{q})^2 \cdots (1 - \frac{1}{q^k})^2}
\end{aligned}$$

For the third statement, set $x_{z-1, \lambda} = 1$ if λ has k parts and $x_{\phi, \lambda} = 0$ otherwise in the cycle index of the unitary groups. As for the general linear groups,

$$\begin{aligned}
P_{U, n}(k, q) &= [u^n] \frac{1}{1-u} \sum_{\lambda: \lambda'_1 = k} M_{(-u, -q)}(\lambda) \\
&= [u^n] \frac{(-u)^k \prod_{r=1}^{\infty} (1 - \frac{-u}{(-q)^{k+r}})}{(1-u) |GL(k, -q)|} \\
&= \frac{1}{|U(k, q)|} [u^{n-k}] \frac{1}{1-u} \sum_{i=0}^{\infty} \frac{(-1)^i (-u(-q)^{-k})^i}{((-q)^i - 1) \cdots (-q - 1)} \\
&= \frac{1}{|U(k, q)|} \sum_{i=0}^{n-k} \frac{(-1)^i (-q)^{\binom{i}{2}}}{(-q)^{ki} |U(i, q)|}
\end{aligned}$$

For the fourth statement argue as for the general linear groups to conclude that:

$$\begin{aligned}
P_{U, \infty}(k, q) &= \lim_{n \rightarrow \infty} [u^n] \frac{1}{1-u} \sum_{\lambda: \lambda'_1 = k} M_{(-u, -q)}(\lambda) \\
&= \sum_{\lambda: \lambda'_1 = k} P_{\frac{1}{(-q)^i}, \frac{1}{(-q)^{i-1}}, 0, \frac{1}{-q}}(\lambda) \\
&= \frac{\prod_{r=k+1}^{\infty} (1 + \frac{1}{(-q)^r})}{|U(k, q)|} \\
&= [\prod_{r=1}^{\infty} (1 - \frac{1}{(-q)^r})] \frac{(\frac{1}{q})^{k^2}}{\prod_{s=1}^k (1 + \frac{1}{(-q)^s}) (1 - \frac{1}{(-q)^s})} \\
&= [\prod_{r=1}^{\infty} (1 + \frac{1}{(-q)^r})] \frac{(\frac{1}{q})^{k^2}}{(1 - \frac{1}{q^2}) \cdots (1 - \frac{1}{q^{2k}})}
\end{aligned}$$

□

Remark The reason that the formulas for $P_{GL, \infty}(k, q)$ and $P_{U, \infty}(k, q)$ factor is because the random variables $h_i(T)$ defined from the Young Tableau Algorithm (see the comments preceding Theorem 4) are independent geometrics.

Rudvalis and Shinoda obtained, after many pages of labor, the following analogous formulas for the symplectic and orthogonal groups:

$$\begin{aligned}
P_{Sp, \infty}(k, q) &= [\prod_{r=1}^{\infty} \frac{1}{1+x^r}] \frac{x^{\frac{k^2+k}{2}}}{(1-x) \cdots (1-x^k)} \\
P_{O, \infty}(k, q) &= [\prod_{r=1}^{\infty} \frac{1}{1+x^r}] \frac{x^{\frac{k^2-k}{2}}}{(1-x) \cdots (1-x^k)}.
\end{aligned}$$

It would be marvellous if there are analogs of the Young Tableau Algorithm for the unipotent conjugacy classes of the symplectic and orthogonal groups. This should lead to a probabilistic interpretation of the products in the Rudvalis/Shinoda formulas. Chapters 5 and 6 of Fulman [1] give some preliminary results in this direction.

Application 3: Work of Lusztig on nilpotent matrices of a given rank

This application uses Theorem 4 (which was proved probabilistically) to prove results of Lusztig [10]. The two theorems which follow were sufficiently nontrivial for Lusztig to devote a note toward them. We found them independently.

Theorem 6 (*Lusztig [10]*) *The number of rank $n - k$ nilpotent $n \times n$ matrices is:*

$$\frac{|GL(n, q)|}{|GL(k, q)|} \frac{(1 - \frac{1}{q^k}) \cdots (1 - \frac{1}{q^{n-k+1}})}{q^{n-k} (1 - \frac{1}{q}) \cdots (1 - \frac{1}{q^{n-k}})}$$

PROOF: Adding the identity show that it suffices to count unipotent matrices in $GL(n, q)$ with a k dimensional fixed space. In the cycle index for the general linear groups, set $x_{z-1, \lambda} = x^{|\lambda|}$ if λ has k parts and $x_{\phi, \lambda} = 0$ otherwise. By Lemma 4 and Theorem 4, the sought number is:

$$\begin{aligned} & |GL(n, q)| [(ux)^n] \frac{1}{1-u} \frac{(ux)^k}{|GL(k, q)|} \frac{\prod_{r=1}^{\infty} (1 - \frac{u}{q^r})}{\prod_{r=1}^k (1 - \frac{ux}{q^r})} \\ &= \frac{|GL(n, q)|}{|GL(k, q)|} [(ux)^{n-k}] \frac{1}{1-u} \frac{\sum_{i=0}^{\infty} \frac{(-u)^i}{(q^i-1) \cdots (q-1)}}{\prod_{r=1}^k (1 - \frac{ux}{q^r})} \\ &= \frac{|GL(n, q)|}{|GL(k, q)|} [(ux)^{n-k}] \frac{1}{\prod_{r=1}^k (1 - \frac{ux}{q^r})} \\ &= \frac{|GL(n, q)|}{|GL(k, q)|} \frac{1}{q^{n-k}} \frac{(1 - \frac{1}{q^k}) \cdots (1 - \frac{1}{q^{n-k+1}})}{(1 - \frac{1}{q}) \cdots (1 - \frac{1}{q^{n-k}})} \end{aligned}$$

The first equality used Lemma 6 and the third equality used Lemma 3. $\square$

Theorem 7 is the corresponding result for the unitary groups. Lusztig actually counted certain nilpotent matrices, but our statement is equivalent. This can be seen using the so-called ‘‘Cayley Transform’’ between unipotent and nilpotent matrices (page 177 of Humphreys [8]).

Theorem 7 (*Lusztig [10]*) *The number of unipotent elements of $U(n, q)$ with a k dimensional fixed space is:*

$$\frac{|U(n, q)|}{|U(k, q)|} \frac{(1 - \frac{1}{(-q)^k}) \cdots (1 - \frac{1}{(-q)^{n-k+1}})}{q^{n-k} (1 - \frac{1}{(-q)}) \cdots (1 - \frac{1}{(-q)^{n-k}})}$$

PROOF: Arguing as in Theorem 6, the sought number is:

$$|U(n, q)| [(ux)^n] \frac{1}{1-u} \frac{(-ux)^k}{|GL(k, q)|} \frac{\prod_{r=1}^{\infty} (1 - \frac{-u}{(-q)^r})}{\prod_{r=1}^k (1 - \frac{-ux}{(-q)^r})}$$

$$\begin{aligned}
&= \frac{|U(n, q)|}{|U(k, q)|} [(ux)^{n-k}] \frac{1}{1-u} \frac{\sum_{i=0}^{\infty} \frac{(u)^i}{((-q)^i - 1) \cdots (-q - 1)}}{\prod_{r=1}^k (1 - \frac{-ux}{(-q)^r})} \\
&= \frac{|U(n, q)|}{|U(k, q)|} [(ux)^{n-k}] \frac{1}{\prod_{r=1}^k (1 - \frac{-ux}{(-q)^r})} \\
&= \frac{|U(n, q)|}{|U(k, q)|} \frac{1}{q^{n-k}} \frac{(1 - \frac{1}{(-q)^k}) \cdots (1 - \frac{1}{(-q)^{n-1}})}{(1 - \frac{1}{-q}) \cdots (1 - \frac{1}{(-q)^{n-k}})}
\end{aligned}$$
